Atmospheric rivers and their associated flood and hazard risks occur globally and influence climate and water extremes.

NOAA ESRL

Over 90% of poleward moisture transport at midlatitudes is by ARs that take up only ~10% of the zonal circumference (Zhu and Newell 1998).

In the west, ARs account for ~40% of annual precipitation and most floods.

Atmospheric rivers → extreme precipitation → snowpack loading → avalanches

Most often, the coastal mountains (Sierra Nevada and Cascades) feel the wrath of atmospheric rivers.

If the atmospheric river (AR) is directed towards lower mountains, it can affect inland mountains. Here, snowpacks are shallower and weaker, so heavy snowfall increases avalanche hazard. While avalanche deaths during ARs are most frequent near the coast, the number of deaths per AR increases as one moves inland.

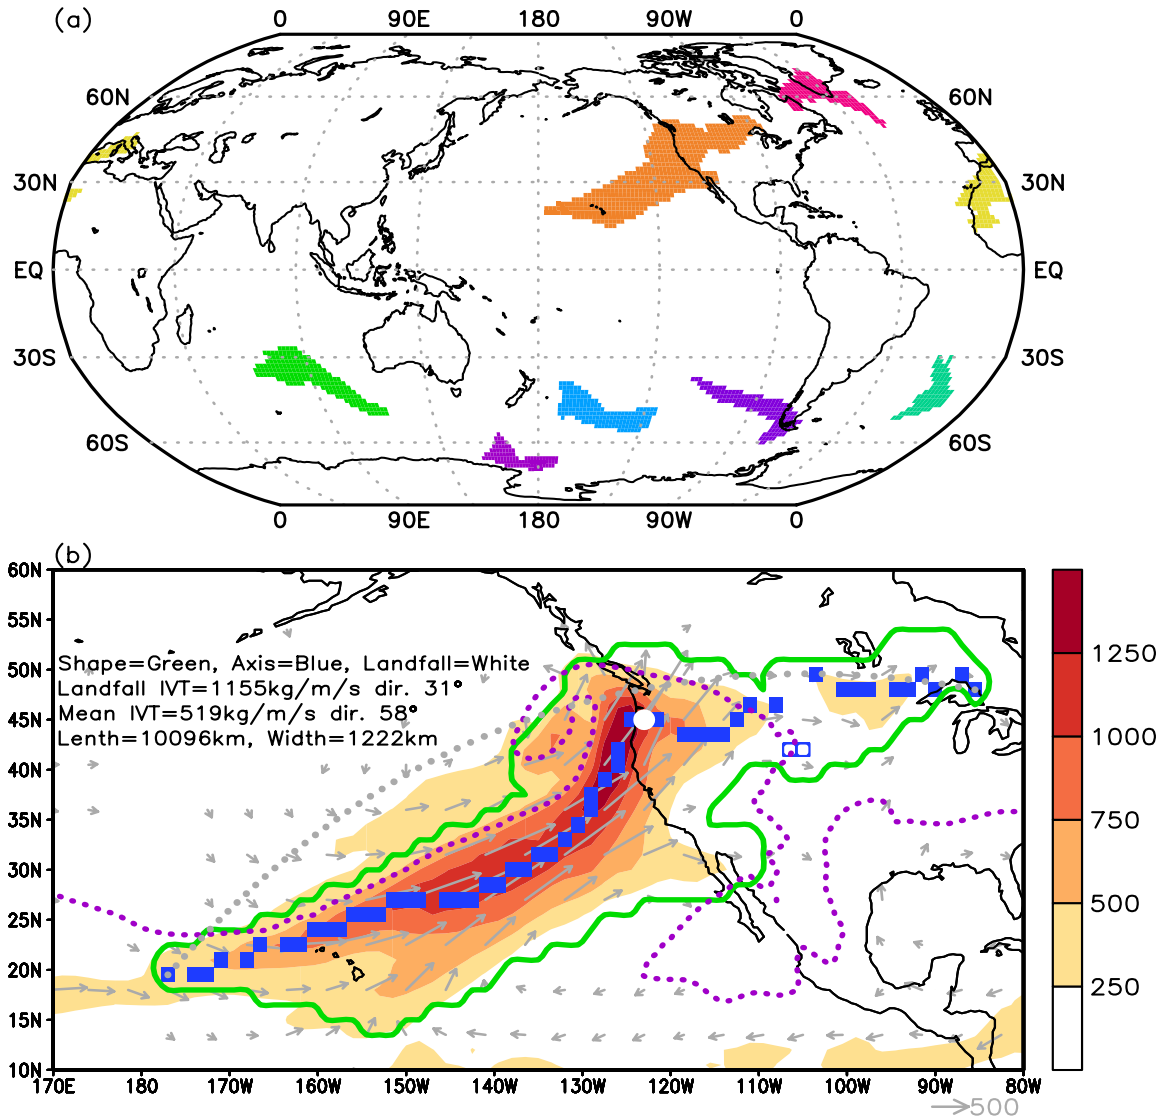

Figure from Desert Research Institute

A global, objective algorithm for AR identification

(Guan and Waliser 2015)

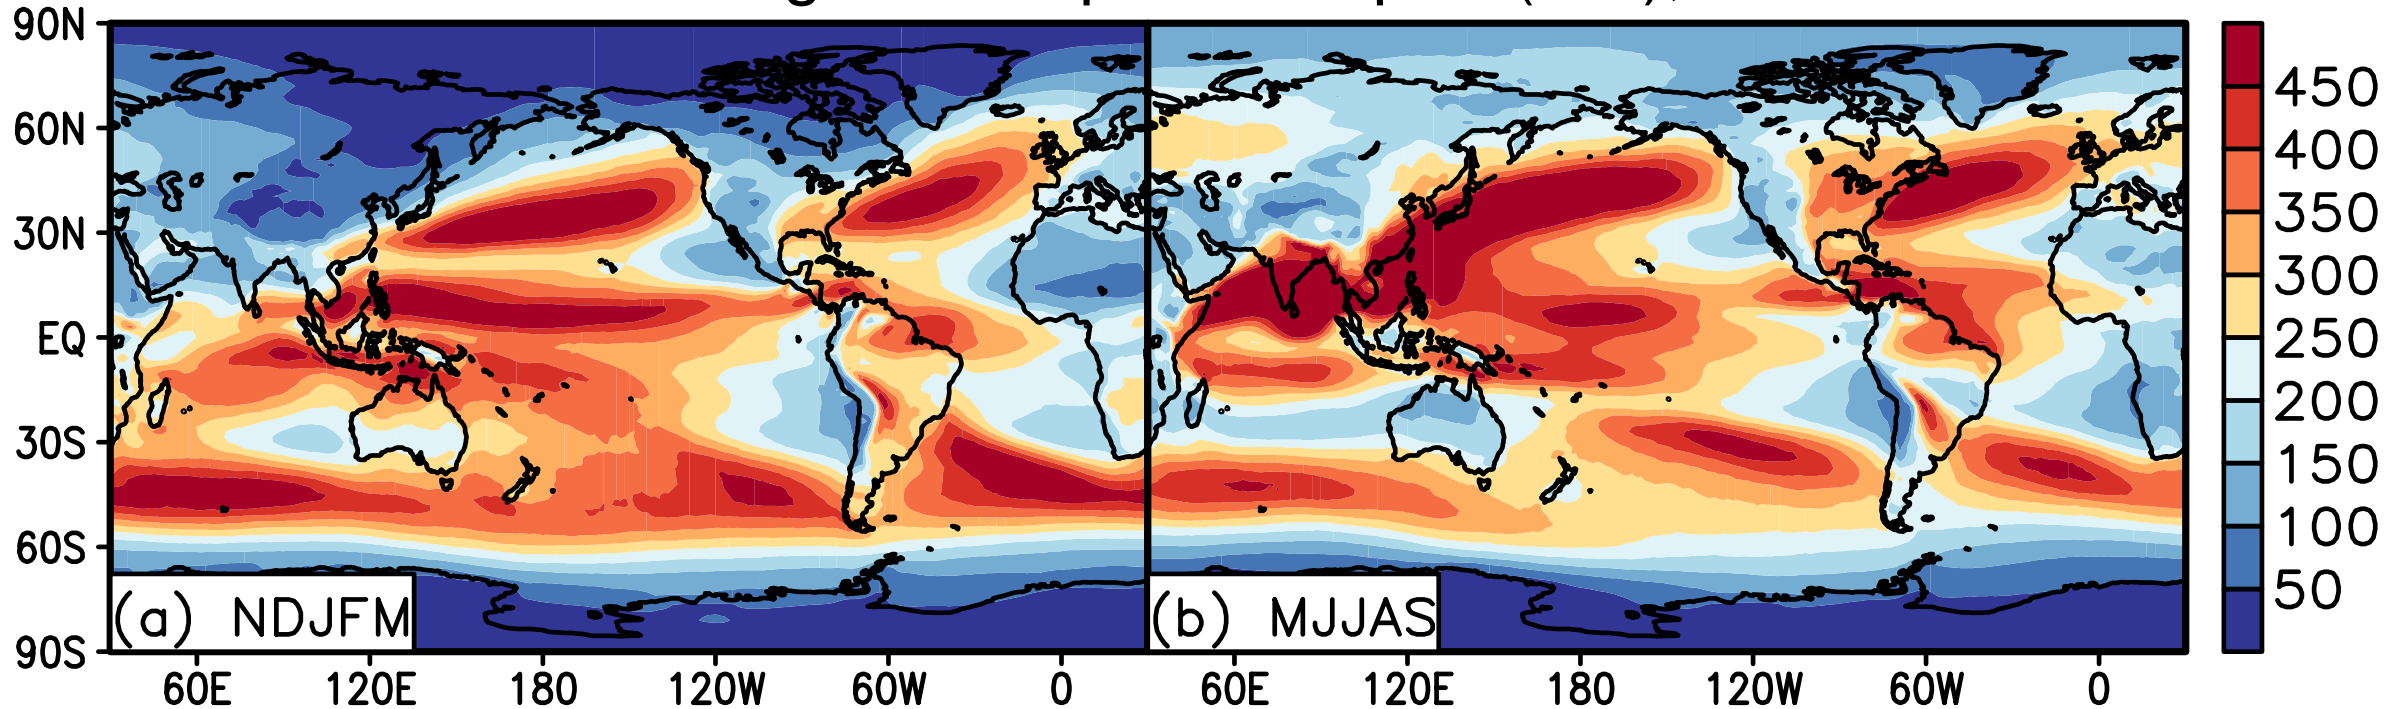

- Based on Integrated Vapor Transport (IVT) fields and a number of common AR criteria (e.g. Ralph et al. 2004)
- Applied to global hindcast/forecast systems and reanalysis datasets
- Code and databases available at: <https://ucla.box.com/ARcatalog>
- Databases include AR Date, $IVT_{x,y}$, Shape, Axis, Landfall Location, etc.
- Used for GCM evaluation (Guan et al. 2017, in revision), climate change projections (Espinoza et al. 2017, submitted), & forecast skill assessment (DeFlorio et al. 2017a and 2017b, in revision)

Global AR Climatology

Guan and Waliser 2015

Based on Integrated Vapor Transport (IVT), 1997-2014

Intensity threshold:

$\text{IVT} > \max(85\text{th percentile}, 100 \text{ kg m}^{-1} \text{s}^{-1})$

Geometry threshold:

$\text{Length} > 2000 \text{ km}, \text{Length/Width} > 2$

Key Research Question

What is the limit of **subseasonal** (1-week to 1-month) prediction skill of **2-week AR occurrence**, and how does it vary as a function of season, region, and certain large-scale background climate conditions?

The **S2S database**: our toolbox for assessing global AR subseasonal prediction skill

- Suite of real-time forecasts and several decades of **hindcasts** from 11 operational forecast models
- Maximum **lead time** ranging from **32 days to 60 days**
- Hindcast ensemble size ranging from 1 to 33
- Variety of forecasting configurations and other model parameters (**heterogeneity** amongst models)
 - “dataset of opportunity”

The S2S Database: a joint WCRP-WWRP Project

	Time-range	Resol.	Ens. Size	Freq.	Hcsts	Hcst length	Hcst Freq	Hcst Size

Summary: **subseasonal** AR prediction skill

- **Subseasonal** (1-week to 1-month lead time) AR prediction skill evaluated globally for the first time (DeFlorio et al. 2017, in prep)
 - counts **#AR days per two weeks** as a function of lead time ("**AR2wk**"); necessary to use an aggregate statistic for subseasonal prediction of chaotic, episodic events
- Observed pattern of seasonal mean of AR2wk strongly resembles global pattern of daily AR frequency (Guan and Waliser 2015)
- Large **model biases** of up to **1-2 AR days per 2 weeks** over **Kuroshio Extension and Indian Monsoon regions** in MJJAS
- ECMWF forecast system outperforms a reference skill forecast based on monthly climatology at **1-week (7-day to 21-day lead window)** in **all four global regions**; up to 2-week (14-day to 28-day lead window) in South Pacific regions
- **Higher** prediction skill over the **North Pacific/Western U.S.** region:
 - at **0-week and 1-week** lead time during **+PNA** relative to -PNA
 - at **1-week and 2-week** lead time during **MJO phase 7** relative to "all days" forecast (but not quite at 95% confidence)

Ongoing and Future Work

- **Experimental real-time subseasonal** (2-week lead) **forecasts** of western U.S. AR **frequency and intensity** using ECMWF and NCEP forecast systems
 - Collaboration with CW3E at UCSD-SIO
 - Marty Ralph
 - Aneesh Subramanian
 - Sasha Gershunov
- **Multi-model** evaluation of subseasonal AR prediction skill
